
Base station battery pack resistance

What is the resistance of a battery pack?

The resistance of a battery pack depends on the internal resistance of each cell and also on the configuration of the battery cells (series or parallel). The overall performance of a battery pack depends on balancing the internal resistances of all its cells.

What makes a telecom battery pack compatible with a base station?

Compatibility and Installation Voltage Compatibility: 48V is the standard voltage for telecom base stations, so the battery pack's output voltage must align with base station equipment requirements. Modular Design: A modular structure simplifies installation, maintenance, and scalability.

What are the parameters of a battery pack?

Assuming that all battery cells are identical and have the following parameters: $I_{cell} = 2 \text{ A}$, $U_{cell} = 3.6 \text{ V}$ and $R_{cell} = 60 \text{ m}\Omega$, calculate the following parameters of the battery pack: current, voltage, internal resistance, power, power losses and efficiency.

How do you find the internal resistance of a battery pack?

If each cell has the same resistance of $R_{cell} = 60 \text{ m}\Omega$, the internal resistance of the battery pack will be the sum of battery cells resistances, which is equal with the product between the number of battery cells in series N_s and the resistance of the cells in series R_{cell} . $R_{pack} = N_s \cdot R_{cell} = 3 \cdot 0.06 = 180 \text{ m}\Omega$
