# Large power station turbine generator

What does a turbine generator do?

A turbine generator must supply the power system of an electric utility or an industrial enterprise with the active and reactive power needed, respectively, to supply the load needs of all users of power, and to maintain the voltages in the power system to keep it operating effectively.

How does an electrical generator work in a power plant?

An electrical generator in a power plant converts mechanical energy, usually from a rotating turbine, into electrical energy. As the turbine spins the generator rotor, the resulting motion of the magnetic field relative to the stationary copper coils induces an electric current in the stator windings.

What is the primary requirement of a turbine generator?

The primary requirement of a turbine generator is to provide electric power continuously or for relatively short peak-load periods as needed, and to do so reliably and economically. A generator is also normally required to provide voltage support to the system by supplying the needed reactive power. See the discussion in Section VIII.B.

How do electric power stations work?

Electrical power stations use large steam turbines driving electric generators to produce most of the world's electricity. The advent of large steam turbines made central-station electricity generation part, since reciprocating steam engines of large rating became very bulk, and operated slow speed.
